

Osc - 1

Perhaps the most ubiquitous motion in the universe:
"oscillatory motion". Results when any system
is moved away from stable equilibrium.

Last chapter, we noted any $U(x)$ can be Taylor ^{expanded}

$$U(x) \approx \underbrace{U(x_0)}_{\text{irrelev. constant}} + \underbrace{U'(x_0)}_{=0 \text{ if } x_0 = \text{equilib}} (x-x_0) + \frac{U''(x_0)}{2!} (x-x_0)^2 + \dots$$

So $U \sim cx^2$ and $F = -kx$

It's "mass on a Spring",

Hooke's law. A good model

for many situation!

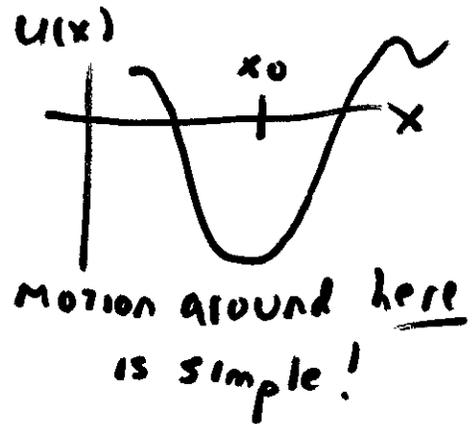

We'll start here, + then add physics (e.g.

damping or time-dependent driving) to get

ever richer ~~more~~ ^{models}

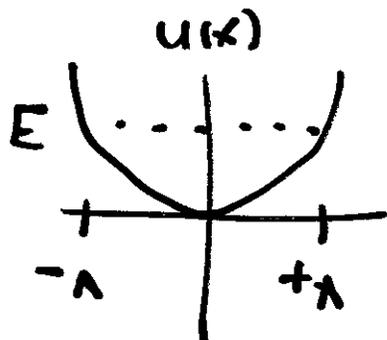

Examples:

Molecules, quarks in nuclei,
RLC "oscillator" circuits
~~or~~ crystals,

Osc - 2

When $F = -kx$, $U(x) = - \int_{x_0}^x \vec{F} \cdot d\vec{x} = - \int_0^x (-kx') dx' = \frac{1}{2} kx^2$

This is SHM, simple harmonic motion

"A" is the amplitude (turn around pt)

At endpoints, it's clear $E = \frac{1}{2} kA^2$.

Newton: $F = ma$ so $m\ddot{x} = -kx$, or

$$\ddot{x} = -\omega^2 x \quad \text{with } \omega \equiv \sqrt{k/m}$$

We've seen this ODE many times (Ch. 1 "pendulum", e.g.)

It's a 2nd order linear, homogenous ODE.

So, expect 2 linearly independent sol'n's.

We know the sol'n, it's:

$$x(t) = B_1 \cos \omega t + B_2 \sin \omega t$$

check (plug it in + see that it works).

sin & cos are independent fns, B_1 & B_2 are any constants (determined by initial conditions)

Osc - 3

There are other ways to write / think about this sol'n, like e.g. $x(t) = C_1 e^{i\omega t} + C_2 e^{-i\omega t}$

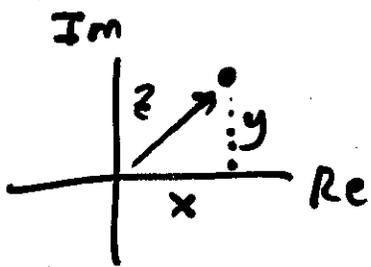

So, to see this, let's take a brief digression for

COMPLEX #'S (See Boas ch 2, + Taylor 2.6.)

These arise from $\sqrt{\text{neg #'s}}$. We define $i \equiv \sqrt{-1}$

A general complex # is $z = x + iy$
 $\equiv \text{Re}(z) + i \text{Im}(z)$

you can "draw" any complex # in the "complex plane"

This reminds me of polar coords,
+ we define

$$|z| = \sqrt{x^2 + y^2} = \sqrt{(\text{Re}(z))^2 + (\text{Im}(z))^2}$$

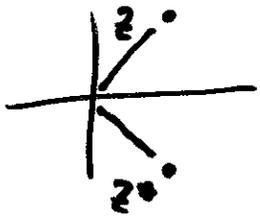

Modulus of z , or magnitude.

Note that x^2 & y^2 are both positive (the "i" is not part of y , it's been pulled out)

OSC -4

Definition: If $z = x + iy$, then

$$z^* = x - iy = \text{"complex conjugate"}$$

Note $z z^* = x^2 - i^2 y^2 = x^2 + y^2$, so

$$|z| = \sqrt{z z^*}$$

Can also divide, e.g. $\frac{2+i}{3-i} = \frac{2+i}{3-i} \cdot \left(\frac{3+i}{3+i}\right)$ ← the trick!

$$= \frac{6 + 5i + i^2}{9 + 1} = \frac{5 + 5i}{10} = \frac{1}{2} + \frac{i}{2}$$

↳ careful!

Recall our Taylor series:

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots \quad \text{for any } x$$

$$\sin x = x - \frac{x^3}{3!} + \dots$$

$$\cos x = 1 - \frac{x^2}{2!} + \dots$$

Now check it out: $e^{i\theta} = 1 + i\theta + \frac{(i\theta)^2}{2!} + \frac{(i\theta)^3}{3!} + \dots$

$$= 1 - \frac{\theta^2}{2!} + \dots + i \left(\theta - \frac{\theta^3}{3!} + \dots \right)$$

$$e^{i\theta} = \cos \theta + i \sin \theta$$

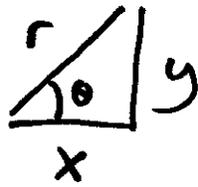

Euler's Formula.

Very useful !!

osc - 5

just look at picture!

Using Euler:

$$z = x + iy = r(\cos\theta + i\sin\theta) \\ = |z| e^{i\theta}$$

Multiplying + Dividing is very easy with this notation:

If $z_1 = r_1 e^{i\theta_1}$ & $z_2 = r_2 e^{i\theta_2}$

$$z_1 z_2 = (r_1 r_2) e^{i(\theta_1 + \theta_2)}$$

$$z_1 / z_2 = (r_1 / r_2) e^{i(\theta_1 - \theta_2)}$$

Power $(z_1)^\alpha = r_1^\alpha e^{i\alpha\theta_1}$

Convince yourself!
 $i = e^{i\pi/2}$

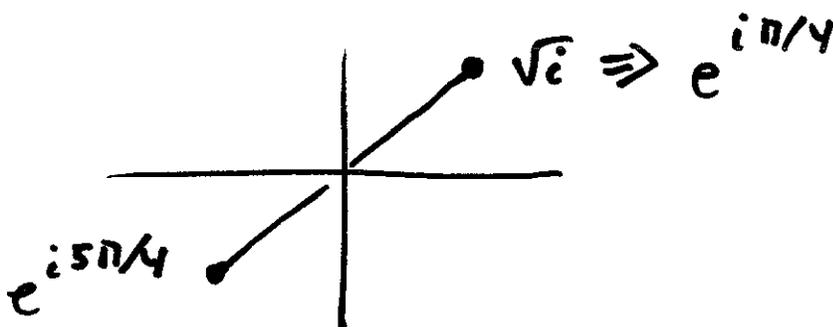

so e.g. $\sqrt{i} = (i)^{1/2} = (e^{i\pi/2})^{1/2} = e^{i\pi/4} = \frac{1}{\sqrt{2}} + \frac{i}{\sqrt{2}}$

Actually there's another root, because $i = e^{i5\pi/2}$ also!

this is $e^{i(2\pi + \pi/2)}$

and $(e^{i5\pi/2})^{1/2} = e^{i5\pi/4} = -\frac{1}{\sqrt{2}} - \frac{i}{\sqrt{2}}$

(There are no different answers, though.)

Osc - 6.

$$\begin{aligned} \text{Note: } e^{i\theta} &= \cos\theta + i\sin\theta &= \operatorname{Re} e^{i\theta} + i \operatorname{Im} e^{i\theta} \\ e^{-i\theta} &= \cos\theta - i\sin\theta &= \operatorname{Re} e^{-i\theta} - i \operatorname{Im} e^{-i\theta} \end{aligned}$$

$$\Rightarrow \cos\theta = \frac{e^{i\theta} + e^{-i\theta}}{2} = \operatorname{Re} e^{i\theta}$$

$$\sin\theta = \frac{e^{i\theta} - e^{-i\theta}}{2i} = \operatorname{Im} e^{i\theta}$$

These will prove handy to us soon when we have integrals like

$$\text{e.g. } \int_{-\pi}^{\pi} \cos 3x \cos 2x \, dx = \int_{-\pi}^{\pi} \frac{e^{i3x} + e^{-i3x}}{2} \cdot \frac{e^{i2x} + e^{-i2x}}{2} \, dx$$

$$= \int_{-\pi}^{\pi} \frac{e^{i5x} + e^{-ix} + e^{+ix} + e^{-i5x}}{4} \, dx = \int_{-\pi}^{\pi} \frac{\cos 5x + \cos x}{2} \, dx$$

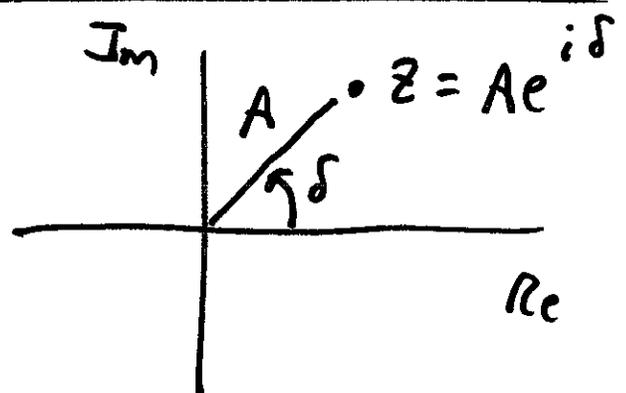

$$= \frac{1}{10} \sin 5x \Big|_{-\pi}^{\pi} + \frac{1}{2} \sin x \Big|_{-\pi}^{\pi} = 0 + 0 = 0!$$

(we'll return to this soon)

Bottom line ↗

Picture complex #'s

as points in complex plane

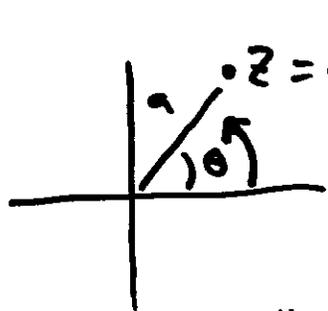

Osc - 7

What's this got to do with our 2nd order ODE?

SHM is very closely connected to simple rotations.

Consider a point rotating (ccw) in the complex plane

$z = ae^{i\theta}$ with steady rate, $\theta = \omega t$

i.e. $z(t) = ae^{i\theta(t)} = a \cos \omega t + i a \sin \omega t$

So " $a \cos \omega t$ " & " $a \sin \omega t$ " are Re & Im parts of this $z(t)$

Return to $\ddot{x} = -\omega^2 x(t)$

We know $x(t) = C_1 e^{i\omega t} + C_2 e^{-i\omega t}$ → Plug it in, works (check!)

(2 constants, 2 independent fns, as there should be).

But we can relate these to our familiar sin's + cos's:

$$x(t) = C_1 (\cos \omega t + i \sin \omega t) + C_2 (\cos \omega t - i \sin \omega t)$$

$$= (C_1 + C_2) \cos \omega t + i (C_1 - C_2) \sin \omega t$$

$$= B_1 \cos \omega t + B_2 \sin \omega t$$

So these 2 different "forms" of sol'n are mathematically

equivalent. $B_1 = C_1 + C_2$, $B_2 = i (C_1 - C_2)$

$$\underline{\underline{\text{or}}}$$

$$C_1 = \frac{B_1 - i B_2}{2} \quad C_2 = \frac{B_1 + i B_2}{2}$$

OSC - 8

Consider a specific initial condition, $x(0) = A$, $\dot{x}(0) = 0$.

$$x(t) = C_1 e^{i\omega t} + C_2 e^{-i\omega t} \quad \underline{\underline{\text{or}}} \quad x = B_1 \cos \omega t + B_2 \sin \omega t$$

$$x(0) = A = C_1 + C_2 \quad \underline{\underline{\text{or}}} \quad A = B_1 = 0$$

$$\dot{x}(t) = C_1 i\omega e^{i\omega t} - C_2 i\omega e^{-i\omega t} \quad \underline{\underline{\text{or}}} \quad \dot{x}(t) = -B_1 \omega \sin \omega t + B_2 \omega \cos \omega t$$

$$\text{so } \dot{x}(0) = 0 = C_1 (i\omega) - C_2 i\omega \quad \underline{\underline{\text{or}}} \quad 0 = B_2 \omega$$

$$\underbrace{\hspace{15em}}$$

$$\underbrace{\hspace{15em}}$$

conclusion $C_1 = C_2$

$$B_2 = 0$$

and, $C_1 = C_2 = A/2$

and $B_1 = A$

so

$$x(t) = \frac{A}{2} (e^{i\omega t} + e^{-i\omega t}) \quad \underline{\underline{\text{or}}} \quad x = A \cos \omega t$$

$$= A \operatorname{Re} e^{i\omega t}$$

← of course, these are the same sol'n!

It is powerful, in general, to think of SHM as $\operatorname{Re}(\text{complex sol'n})$

$e^{i\omega t}$ is called a "phasor". Think of it as a complex representation of a sin wave. (And, convince yourself

that if $x(0) = 0$, $\dot{x}(0) = +V_0$, then $x(t) = \frac{V_0}{\omega} \sin \omega t$)

Osc - 9

Recall, we're solving $\ddot{x} = -\omega^2 x$, + found general sol'n

$$x(t) = C_1 e^{i\omega t} + C_2 e^{-i\omega t} \quad \underline{\underline{\text{or}}} \quad B_1 \cos \omega t + B_2 \sin \omega t$$

these are equivalent, $B_1 = C_1 + C_2$, $B_2 = i(C_1 - C_2)$

In either case, these are periodic functions, with

$$\text{Period } T = 2\pi/\omega \quad (= 2\pi\sqrt{m/k} \text{ for mass on spring})$$

Proof for $e^{i\omega t}$: $e^{i\omega(t+T)} = e^{i\omega t} e^{i\omega T} = e^{i\omega t} e^{i\omega 2\pi/\omega}$
 $= e^{i\omega t} e^{i2\pi}$
 $= e^{i\omega t}$

definition of a period! \curvearrowright

Period is independent of B's or C's!

Note that if $\ddot{z} = -\omega^2 z$, with $z = \overset{\text{Re } z}{a} + \overset{i \text{Im}(z)}{b}$,

then $\text{Re } \ddot{z} = -\omega^2 \text{Re } z$; so when you find a complex sol'n, you can always "take the real part" + you still have a sol'n! This is one way to understand why we use complex sol'ns to "real" physics problems, the math of $e^{i\omega t}$ is easier than sin's + cos's!

there's yet a 3rd way to write / think of our general sol'n
 (It's particularly useful when $x(0)$ is nothing special, i.e. neither "A" nor "0") I claim

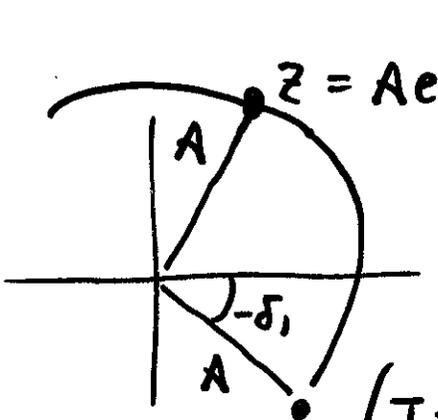

$x(t) = A \cos(\omega t - \delta)$ is again equivalent, a general sol'n to $\ddot{x} = -\omega^2 x$
 2 independent constants, as needed!

Just use $\cos(a+b) = \cos a \cos b - \sin a \sin b$, so

$$x(t) = \underbrace{(A \cos \delta)}_{B_1} \cos \omega t + \underbrace{(A \sin \delta)}_{B_2} \sin \omega t$$

$$= B_1 \cos \omega t + B_2 \sin \omega t, \text{ ah ha, it is}$$

our exact same general sol'n! Picture this

$z = Ae^{i(\omega t - \delta)}$, and $\text{Re } z = A \cos(\omega t - \delta)$

This is just simple rotation in complex plane. This sol'n is again equivalent.

(It's useful when $x(0) = A \cos \delta$ is not at the "extreme" spot)

(See Taylor p.167 for more!)

Osc - 11

In this form, $x(t) = A \cos(\omega t - \delta)$, it's also particularly easy to look at energy.

Note: $\dot{x}(t) = -A\omega \sin(\omega t - \delta)$

so $KE = \frac{1}{2} m \dot{x}^2(t) = \frac{1}{2} m A^2 \omega^2 \sin^2(\omega t - \delta)$

$PE = \frac{1}{2} k x^2(t) = \frac{1}{2} k A^2 \cos^2(\omega t - \delta)$

But $\omega^2 = k/m$, so $m\omega^2 = k$, and thus

$T + U = \frac{1}{2} k A^2 (\sin^2(\dots) + \cos^2(\dots)) = \frac{1}{2} k A^2$

Energy is conserved, with the value we notes back on p. 1!

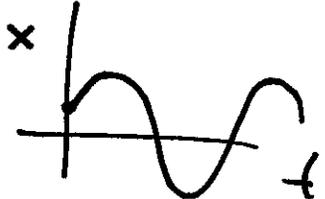

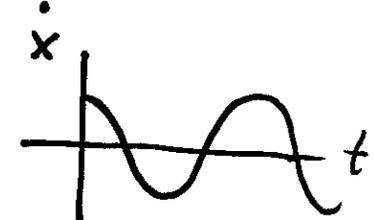

In general, for SHM "Simple Harmonic Motion"

- Periodic (sinusoidal) motion, $x(t) = A \cos(\omega t - \delta)$
- $F = -kx$ Hooke's law, force opposes motion
- $U \propto x^2$ Quadratic potential energy
- Period is independent of Amplitude
- there are 2 independent "constants" determined by initial conditions (e.g. $x(0)$ & $\dot{x}(0)$)

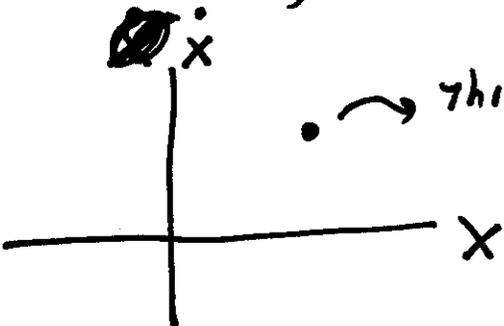

Osc - 12

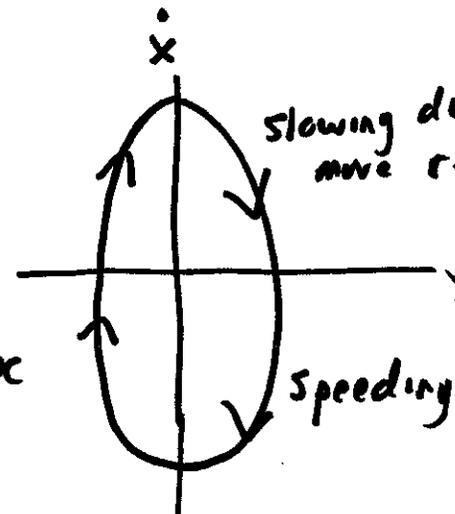

- The 2 "conditions" can also be $x(t_0)$ & $\dot{x}(t_0)$ at some time, (or T and U at some time) or A and δ ("Amplitude and phase shift").

- If you know $x(t_0)$ & $\dot{x}(t_0)$, you know x at all times!

you can visualize  OR 

OR something new, a "phase space diagram":

 \dot{x}
 x \rightarrow This point tells you x & \dot{x} at one time, + then you can watch this point move around as time goes by

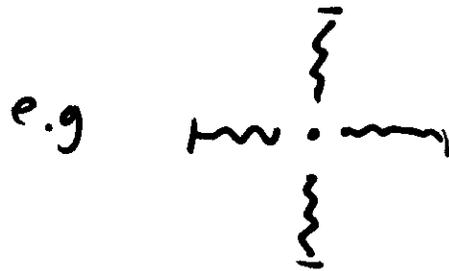

So e.g.  \dot{x}
 x slowing down, as we move right-wards
etc speeding up (neg), moving leftwards

Osc -13.

2-D Harmonic Motion: If you have restoring forces

In 2-D, $m\ddot{x} = -K_x x$

$m\ddot{y} = -K_y y$

If $K_x = K_y = m\omega^2$, this is isotropic

If $K_x \neq K_y$, this is anisotropic

If isotropic, $x(t) = A_x \cos(\omega t - \delta_x)$
 $y(t) = A_y \cos(\omega t - \delta_y)$

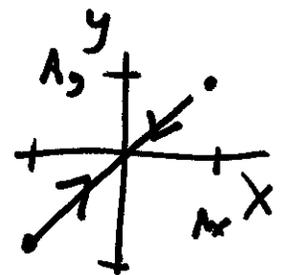

2 constants needed for each dimension

Here it's nice to plot $y(t)$ vs $x(t)$. As time goes by, we "map out" the trajectory

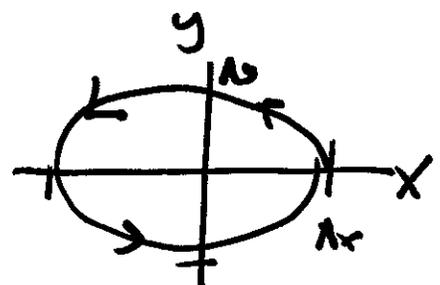

← This is not a phase space plot. It's a real path (in real space, over time)

If $\delta_x = \delta_y$, both are "in phase", + $x = \frac{A_x}{A_y} y$
convince yourself!

If $\delta_y = \delta_x + \pi/2$, $x(t) = A_x \cos(\omega t - \delta_x)$
 $y(t) = A_y \sin(\omega t - \delta_x)$

so $\frac{x^2}{A_x^2} + \frac{y^2}{A_y^2} = 1$. (ccw if $\omega > 0$)

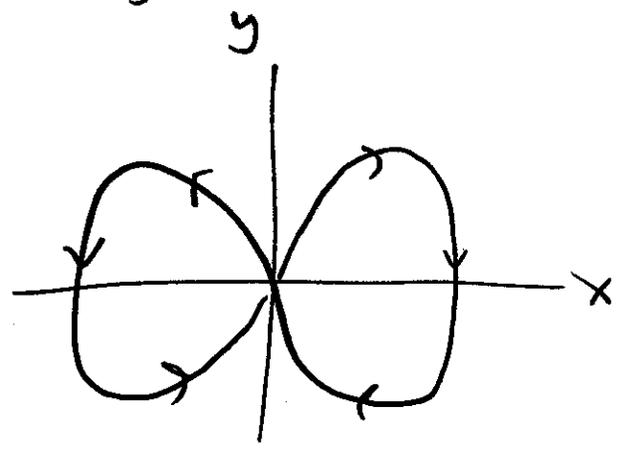

Osc-14

If anisotropic: ω 's are different. Pictures get more complicated, "Lissajous Patterns"

If $\frac{\omega_x}{\omega_y} = \frac{n}{m}$ - ratio of integers then it "repeats" (closes on itself)

If $\frac{\omega_x}{\omega_y}$ is irrational, it does not ever repeat / close

Ex: $\omega_y = 2\omega_x$, so it oscillates twice in y direction for every one in x direction:

Osc-15

Back to 1-D, let's add DAMPING

Consider linear drag, $m\ddot{x} = -kx - b\dot{x}$

(Quadratic drag \Rightarrow non-linear 2nd order ODE, this gets much more complicated). Rewrite Newton as

$$\ddot{x} + \frac{b}{m}\dot{x} + \frac{k}{m}x = 0 \quad \left. \vphantom{\ddot{x}} \right\} \begin{array}{l} \text{A 2nd order, linear, homogeneous} \\ \text{ODE with constant coefficients} \end{array}$$

Many physical systems obey this ODE (mechanical, electrical. \leftarrow RLC circuits, e.g.) • Let's take a

brief digression here to look at 2nd order ODE's

(Boas 8.5) The most general linear 2nd order ODE

$$y'' + P(t)y' + Q(t)y = R(t)$$

\hookrightarrow Homogeneous if $R=0$

- Should find 2 linearly independent sol'n's

- We'll deal with $R(t) \neq 0$ later. (soon!)

Osc - 16

What does "linear" imply? If also homogeneous,

1) If $y_1(t)$ solves it, so does $C y_1(t)$

(Convince yourself! C comes ~~out~~ ^{thru} $d/dt \dots$)

2) If $y_2(t)$ also solves it, so does $y_1(t) + y_2(t)$

(Again, just plug it in to check)

- y_1 and y_2 are "linearly independent" if you cannot find any constants that make $C_1 y_1(t) + C_2 y_2(t) = 0$ for all times (except the trivial $C_1 = C_2 = 0$)

(Think of 2 vectors being independent similarly, $C_1 \vec{v}_1 + C_2 \vec{v}_2$ can't be zero)

There is a nifty quick tool to test if functions are linearly independent, you form the

Wronskian determinant $W = \begin{vmatrix} f_1(t) & f_2(t) \\ f_1'(t) & f_2'(t) \end{vmatrix}$

If $\omega = 0$, they are dependent. If $\omega \neq 0$, independent?

Ex:
$$\begin{vmatrix} \cos \omega t & \sin \omega t \\ -(\sin \omega t) \cdot \omega & (\cos \omega t) \cdot \omega \end{vmatrix} = \omega \cos^2 \omega t + \omega \sin^2 \omega t = \omega \neq 0$$

So $\sin \omega t, \cos \omega t$ are independent (unless $\omega = 0$!)

Ex:
$$\begin{vmatrix} e^{i\omega t} & e^{-i\omega t} \\ i\omega e^{i\omega t} & -i\omega e^{-i\omega t} \end{vmatrix} = -2i\omega \neq 0, \text{ again independent} \\ \text{(unless } \omega = 0 \text{!)}$$

Ex: Can generalize to more fns,

fns $\rightarrow \begin{vmatrix} \cos \omega t & \sin \omega t & e^{i\omega t} \\ -\omega \sin \omega t & \omega \cos \omega t & i\omega e^{i\omega t} \\ -\omega^2 \cos \omega t & -\omega^2 \sin \omega t & -\omega^2 e^{i\omega t} \end{vmatrix}$

1st deriv $\rightarrow \begin{vmatrix} \cos \omega t & \sin \omega t & e^{i\omega t} \\ -\omega \sin \omega t & \omega \cos \omega t & i\omega e^{i\omega t} \\ -\omega^2 \cos \omega t & -\omega^2 \sin \omega t & -\omega^2 e^{i\omega t} \end{vmatrix}$

2nd deriv $\rightarrow \begin{vmatrix} \cos \omega t & \sin \omega t & e^{i\omega t} \\ -\omega \sin \omega t & \omega \cos \omega t & i\omega e^{i\omega t} \\ -\omega^2 \cos \omega t & -\omega^2 \sin \omega t & -\omega^2 e^{i\omega t} \end{vmatrix}$

$$\begin{aligned} & \cos \left[-\omega^3 \cos e^{i\omega t} + i\omega^3 \sin e^{i\omega t} \right] \\ & -\sin \left[-\omega^3 \sin e^{i\omega t} + i\omega^3 \cos e^{i\omega t} \right] \\ & + e^{i\omega t} \left[-\omega^3 \sin^2 + \omega^3 \cos^2 \right] \end{aligned}$$

$$= \omega^3 e^{i\omega t} \left[-\cos^2 + i \sin \cos + \sin^2 - i \sin \cos - \sin^2 + \cos^2 \right]$$

= 0! So they are not all 3 linearly independent,

(that's why we have $A \cos + B \sin$ or $A e^{i\omega t} + B e^{-i\omega t}$)
 but not some combo of 3 or more of these!

Osc - 18

Back to our ODE: $\ddot{x} + \frac{b}{m} \dot{x} + \frac{k}{m} x = 0$

Consider a simple, special case, just as an example

e.g. $\ddot{y} + 3\dot{y} + 2y = 0$

Here's the trick: Consider the operator $D \equiv \frac{d}{dt}$

It's linear: $D(3y) = 3Dy$ and $D(y_1 + y_2) = Dy_1 + Dy_2$

so $D^2 y + 3Dy + 2y = 0$ or $(D^2 + 3D + 2)y = 0$

Now treat this like it was algebra $(D+1)(D+2)y = 0$

This works if $(D+1)y = 0$ or $(D+2)(D+1)y = 0$

or $(D+2)y = 0$.

These are 1st order ODE's, + I know their sol'n -

$(D+1)y = 0 \Rightarrow \dot{y} = -y \Rightarrow y = C_1 e^{-t}$

$(D+2)y = 0 \Rightarrow \dot{y} = -2y \Rightarrow y = C_2 e^{-2t}$

check Wronskian

$$\begin{vmatrix} e^{-t} & e^{-2t} \\ -e^{-t} & -2e^{-2t} \end{vmatrix} = e^{-3t} (-2+1) \neq 0!$$

So $y = C_1 e^{-t} + C_2 e^{-2t}$
is the general
sol'n here.

Osc - 19

In general, $(D-r_1)(D-r_2)y = 0$ is solved by

$$y = C_1 e^{r_1 t} + C_2 e^{r_2 t} \quad (\text{as long as } r_1 \neq r_2, \text{ see } \text{bottom of page } *)$$

Indeed, if r_1 and r_2 are roots of the

"auxiliary algebraic eq'n"

(i.e. From $a\ddot{y}(t) + b\dot{y}(t) + cy = 0$,
auxiliar eq'n is $aD^2 + bD + c = 0$), then roots
of this

$$r_{1,2} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \quad \text{generate our sol'n,}$$

$$y = C_1 e^{r_1 t} + C_2 e^{r_2 t}.$$

* If roots are equal, I claim

$$y(t) = (C_1 + C_2 t) e^{-rt} \quad \text{will solve the ODE.}$$

Can check by plugging in, + use Wronskian to

convince yourself e^{-rt} and te^{-rt} are independent.

Osc 19b

Derivation of the previous claim:

$$(D-r)(D-r)y = 0.$$

clearly $y = c_1 e^{rt}$ is one sol'n.

Let $u(t) = (D-r)y$. so $(D-r)u = 0 \Rightarrow u = c_2 e^{rt}$

thus, $(D-r)y = u = c_2 e^{rt}$. Recall, Boas has a trick to solve this, remember?

$$y' + Py = Q \quad (\text{here, } P = -r, \text{ and } Q = c_2 e^{rt})$$

$$\text{then } I = \int P dt = -rt$$

$$\begin{aligned} \text{and } y &= e^{-I} \int Q e^I dt + C e^{-I} = \\ &= e^{-rt} \int c_2 e^{rt} e^{-rt} dt + C e^{-rt} \\ &= e^{-rt} \cdot c_2 t + C e^{-rt} \\ &= (C + c_2 t) e^{-rt} \end{aligned}$$

Example: $\ddot{y} + \omega_0^2 y = 0$. Sol'n?

Auxiliary eq'n is $(D^2 + \omega_0^2) = 0$

roots are $\pm i\omega_0$, so general sol'n is

$$y = C_1 e^{i\omega_0 t} + C_2 e^{-i\omega_0 t}$$

Precisely our sol'n we've used before!

What about $m\ddot{y} + \frac{b}{m}\dot{y} + \omega_0^2 y = 0$, which is what we've been after? Let's define a damping constant $\beta \equiv \frac{b}{2m}$

So we're solving $\ddot{y} + 2\beta\dot{y} + \omega_0^2 y = 0$

units of $[\beta]$
= units of $[\omega]$

auxiliary eq'n $D^2 + 2\beta D + \omega_0^2 = 0$

roots are $r_{1,2} = \frac{-2\beta \pm \sqrt{4\beta^2 - 4\omega_0^2}}{2} = -\beta \pm \sqrt{\beta^2 - \omega_0^2}$

Assuming $\beta \neq \omega_0$, these roots are distinct, + we have

a sol'n $y(t) = e^{-\beta t} (C_1 e^{+\sqrt{\beta^2 - \omega_0^2} t} + C_2 e^{-\sqrt{\beta^2 - \omega_0^2} t})$

(if $\beta = \omega_0$, we use the trick from prev page, we'll come back to this)

$$\ddot{y} + 2\beta \dot{y} + \omega_0^2 y = 0 \quad (\text{Damped SHM})$$

there are 3 possible cases

- ① $\beta < \omega_0$, "weak damping", $\sqrt{\beta^2 - \omega_0^2}$ is imaginary!
- ② $\beta > \omega_0$, "strong damping", " " real.
- ③ $\beta = \omega_0$, "critical damping", use "double root" trick.

Case ① $\beta < \omega_0$, also called UNDERDAMPED.

$$\sqrt{\beta^2 - \omega_0^2} = i \sqrt{\omega_0^2 - \beta^2} \equiv i \omega_1 \quad (\text{Defines } \omega_1. \text{ For small } \beta, \omega_1 \approx \omega_0)$$

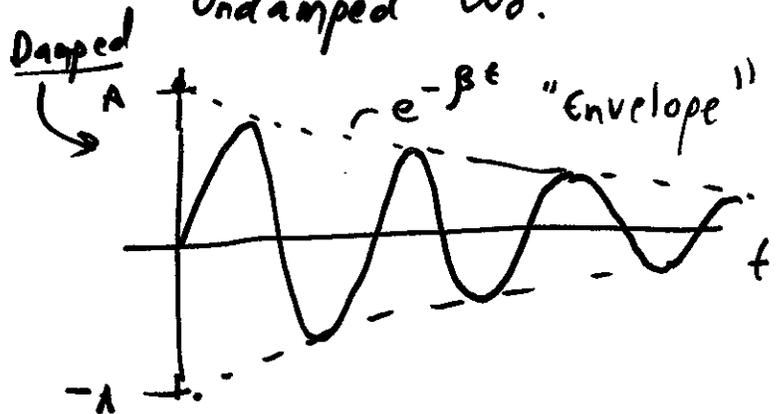

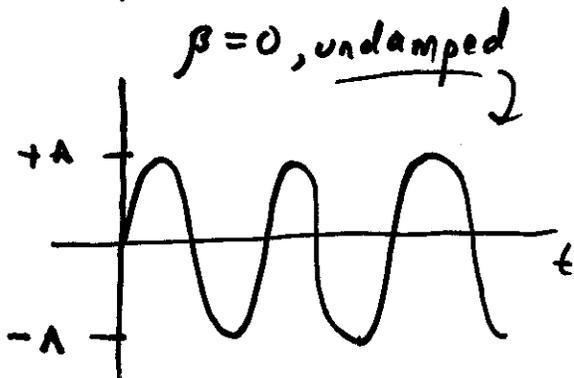

$$y(t) = e^{-\beta t} (C_1 e^{+i\omega_1 t} + C_2 e^{-i\omega_1 t})$$

or, looking back a few pages, can also rewrite as

$$y(t) = \underbrace{e^{-\beta t}}_{\text{"Amplitude" is decaying}} A \cos(\omega_1 t - \delta). \quad \text{Very much like SHM}$$

"Amplitude" is decaying

freq is a bit below "natural" undamped ω_0 .

Osc - 22

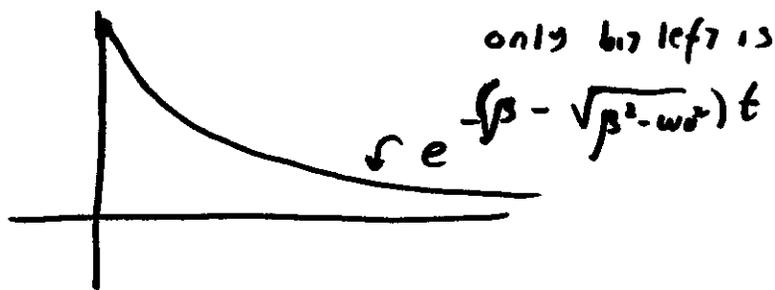

Case 2, $\beta > \omega_0$, "over damped"

$$y(t) = C_1 e^{-\beta t + \sqrt{\beta^2 - \omega_0^2} t} + C_2 e^{-\beta t - \sqrt{\beta^2 - \omega_0^2} t}$$

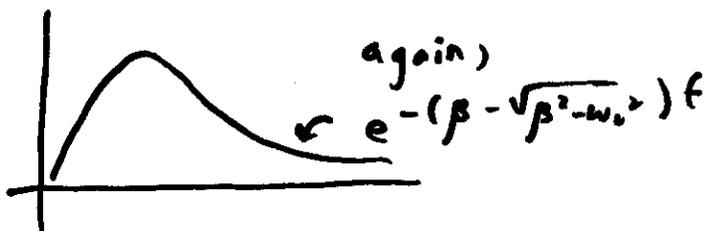

Both terms are dying exponentials. (convince yourself the C_1 term is decaying, the $+$ part is smaller than the $-$ part!)

No oscillations, too much damping! It might cross the axis (once) if you pick C_1 & C_2 cleverly, but no "ringing".

Note: C_2 term has a much more negative coefficient for t so it $\rightarrow 0$ faster. At large t , C_1 term dominates.

if $C_1, C_2 > 0$
so $y(0) > 0$,

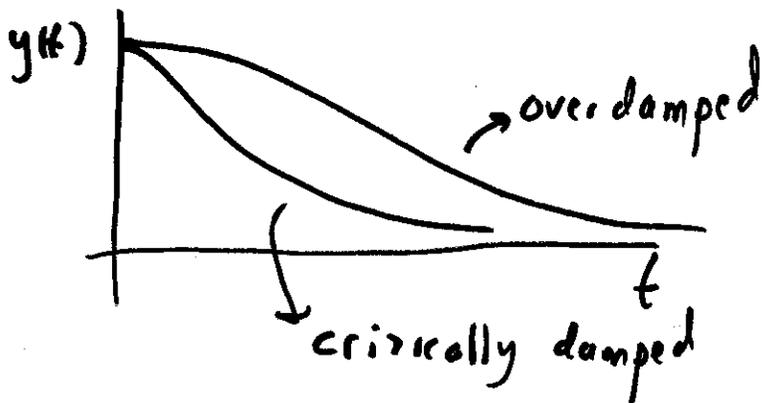

if e.g. $C_2 = -C_1$
so $y(0) = 0$, $\dot{y}(0) > 0$

Note: As β gets bigger, $\beta - \sqrt{\beta^2 - \omega_0^2} \rightarrow 0$, so somewhat surprisingly, large damping in fact slows the rate of decay!

Case 3: Critical damping, $\beta = \omega_0$

Double root of $-\beta$, so $y(t) = (C_1 + C_2 t) e^{-\beta t}$

The dying exponential always "wins" eventually, so this does die away, very much like $e^{-\beta t}$. This is a faster die-off than the $e^{-(\beta - \sqrt{\beta^2 - \omega_0^2})t}$ we had in the overdamped case.

Think of the pneumatic tube on a screen door, or shocks on your car:

Too little damping \Rightarrow oscillations (or banging)

Too much damping \Rightarrow very slow to settle down

critical " \Rightarrow fastest return to equilib w/o oscillations.

Osc - 24

What if we drive / force our oscillator?

$$\ddot{y} + 2\beta \dot{y} + \omega_0^2 y = \underbrace{R(t)}_{\text{in homogeneous}}$$

From Newton, this is $\frac{F(t)}{m}$

(or, e.g. in an RLC circuit, it might be a voltage source)

The approach for inhomogeneous linear ODE's is:

Solve the homogeneous case to get $y_c = C_1 y_1(t) + C_2 y_2(t)$
Complementary

+ then find any particular sol'n y_p .

then $y = y_c + y_p$ is your fully general sol'n w. 2 constants!

We know how to find y_c , so we just need y_p .

Sometimes: "by inspection" works! e.g. $\ddot{y} + 4\dot{y} + 3y = 5$

I claim $y_p = 5/3$ is clearly a sol'n. (Do you see why? Try it!)

General sol'n: Roots of $D^2 + 4D + 3$ are 1 & 3, so

$$\underline{y = Ae^t + Be^{3t} + 5/3} \text{ is the fully general sol'n}$$

(So if $R(t) = R_0 = \text{constant}$, use $y_p = R/\omega_0^2 \dots$)

Osc -25

What if $R(t) = f_0 e^{ct}$ (where c can be imaginary!)

This is really much more general than it looks, because $e^{i\omega t}$ as we've seen has $\cos(\omega t)$ and $\sin \omega t$ "built in", + we can build up any oscillatory $R(t)$ by summing up * sin's + cos's with different ω 's. We'll come back to do that, but this is why this example is so fundamental + essential.

* $\left[\begin{array}{l} \text{Note that if we find } y_{p1} \text{ for } R_1(t) \text{ on the right side} \\ \text{and } y_{p2} \text{ for } R_2(t), \text{ then} \\ y_{p1} + y_{p2} \text{ will solve the ODE with } R = R_1(t) + R_2(t) \end{array} \right.$

We can derive y_p for $R(t) = f_0 e^{ct}$, but the nice thing about y_p is you just need to find anything that works, so the method of "guess and check" is just fine!

Osc - 26

We're solving $\ddot{y} + 2\beta\dot{y} + \omega_0^2 y = f_0 e^{ct}$

+ looking for any y_p . Let's try $y_p(t) = C_3 e^{ct}$!

[This doesn't always work (e.g. if c happens to be one of the roots of the auxiliary eq'n, we'll need to try $C_3 t e^{ct}$, + if it equals a double root, $C_3 t^2 e^{ct}$,

But those are really special cases)

Important: C_3 is not a new "unknown, arbitrary" constant!

This is y_p , we need to plug it in, + the ODE itself will require a very particular value for C_3 , it's not set by

"initial conditions"! Let's do it: $\ddot{y}_p = c^2 y_p$
 $\dot{y}_p = c y_p$

$$\text{so } (c^2 + 2\beta c + \omega_0^2) C_3 e^{ct} = f_0 e^{ct}$$

$$\text{so } C_3 = \frac{f_0}{c^2 + 2\beta c + \omega_0^2}$$

is required, it's fixed!

(This is all good as long as c isn't accidentally a root of the ~~auxiliary~~ auxiliary eq'n, (then the denom $\rightarrow 0$)

Osc - 27

Important example: $R(t) = f_0 e^{i\omega t}$, (oscillating driver)
(here, $c = i\omega$)

$$y_p = c_3 e^{i\omega t} \rightarrow \frac{f_0 e^{i\omega t}}{(-\omega^2 + 2\beta i\omega + \omega_0^2)} = \frac{f_0 e^{i\omega t}}{(\omega_0^2 - \omega^2) + 2\beta i\omega}$$

If the driving force is real, say $f_0 \cos \omega t$, no problem, just take the real part of this sol'n !!

Our $c_3 = f_0 / (\omega_0^2 - \omega^2) + 2\beta i\omega$ is complex. Any complex # can always be written in the form $c_3 = A e^{-i\delta}$
↑
amplitude phase

(Note that "taking the real part" is much easier in this form, $\text{Re}(c_3) = A \cos \delta$.)

Let's pause to work out c_3 , then:

$$\begin{aligned} \text{To get } A = |c_3|, \text{ use } \left| \frac{1}{a+bi} \right| &= \left| \frac{1}{a+bi} \frac{a-bi}{a-bi} \right| \\ &= \frac{|a-bi|}{a^2+b^2} = \frac{1}{\sqrt{a^2+b^2}} \end{aligned}$$

(To get δ , rewrite c_3 in the form ~~$a+bi$~~ $Re + iIm$)

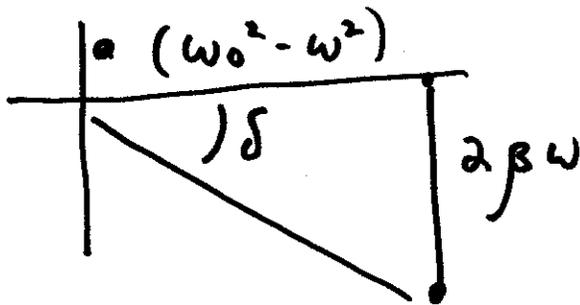

Osc - 28

our $C_3 = \frac{f_0}{(\omega_0^2 - \omega^2) + i \cdot 2\beta\omega}$; so $|C_3| = \frac{f_0}{\sqrt{(\omega_0^2 - \omega^2)^2 + 4\beta^2\omega^2}}$

(use $|\frac{1}{a+bi}| = \frac{1}{\sqrt{a^2+b^2}}$)

also, $C_3 = \frac{f_0}{(\omega_0^2 - \omega^2)^2 + 4\beta^2\omega^2} \cdot [(\omega_0^2 - \omega^2) - 2\beta\omega i]$

so

$\delta = \tan^{-1} \frac{2\beta\omega}{\omega_0^2 - \omega^2}$
from the picture!

It's gotten a little ugly, let's recap:

We're solving $\ddot{y} + 2\beta\dot{y} + \omega_0^2 y = f_0 e^{i\omega t}$

We know how to find $y_c(t)$ (solving "ancillary", homog eq'n)

We just found $y_p(t) = C_3 e^{i\omega t} = A e^{-i\delta} e^{i\omega t}$

(If we have a real driver, $f_0 \cos \omega t$, we'll simply take the Real part of our sol'n, giving $\text{Re}(y_p) = A \cos(\omega t - \delta)$)

Let's do an example!

Osc - 29

Underdamped, driven oscillator. (Like, resonating circuit in your stereo)

Recall, the homogeneous $y_c(t)$ sol'n has an overall $e^{-\beta t}$, so it dies away, it's transient. In general, that sol'n is

$$y_c(t) = A e^{-\beta t} \cos(\omega_1 t - \delta_{tr})$$

these are our 2 arbitrary coefficients, found from initial conditions

so $y(t) = \cancel{y_p} y_p + y_c$

$$= A \cos(\omega t - \delta) + \underbrace{A e^{-\beta t}}_{\text{dies off, hence label "transient"}} \cos(\omega_1 t - \delta_{tr})$$

where $A = \frac{f_0}{\sqrt{(\omega_0^2 - \omega^2)^2 + 4\beta^2 \omega^2}}$

and $\delta = \tan^{-1} 2\beta\omega / \omega_0^2 - \omega^2$

After some time $\gg 1/\beta$, only

$y_p = A \cos(\omega t - \delta)$ remains. (True also if

overdamped, or critically damped, so this is quite general)

• If you drive an oscillator, it settles down by oscillating at the driving frequency (but, phase shifted)

β and ω_1 are as before,
 $\omega_1 = \sqrt{\omega_0^2 - \beta^2}$

Osc -30

Bottom line: $\ddot{y} + 2\beta\dot{y} + \omega_0^2 y = f_0 e^{i\omega t}$

large t sol'n: $y = A \cos(\omega t - \delta)$

A is fixed, it's $f_0 / \sqrt{(\omega_0^2 - \omega^2)^2 + 4\beta^2 \omega^2}$, it's not initial conditions!

δ is fixed, it's $\tan^{-1} 2\beta\omega / \omega_0^2 - \omega^2$, again " " "

ω is the driver's ω , not the natural freq. (neither ω_0 nor ω_1)

The Amplitude $A \propto f_0$, so "strong drivers" \Rightarrow large response

A tells you the "strength of response", the long-term amplitude of motion. Energy in an oscillator $\propto \frac{1}{2} k A^2$,

so it also tells you how much energy the "final state" has.

(For this reason, we're often interested in $|A|^2$.)

A depends (linearly) on f_0 , the driving force, but also

on ω_0 (natural freq), β (damping), + ω (driving freq)

when β is small, interesting things happen, let's investigate.

Resonance

1) In some situations, ω is set somehow, but you can vary or control ω_0 . E.g., if PBS broadcasts a radio wave at 98.5 MHz, that drives your stereo. $\omega = 2\pi \cdot 98.5 \text{ MHz}$. But by twisting a knob (thus varying a capacitance or inductance), you can "tune" ω_0 at will! We'll come back to the details of "RLC circuits" soon.

2) In other situations, ω_0 is set somehow, but you can vary or control the driving frequency ω . (Consider a bridge or building with natural vibrational frequency, driven by a controllable or variable outside force)

Situation 1 is slightly simpler mathematically, but for small drag ($\beta \ll \omega, \omega_0$) both are qualitatively similar.

So, let's ^{1st} consider case 1), ω is fixed, and we are

free to vary ω_0 at will. How does Amplitude, A ,

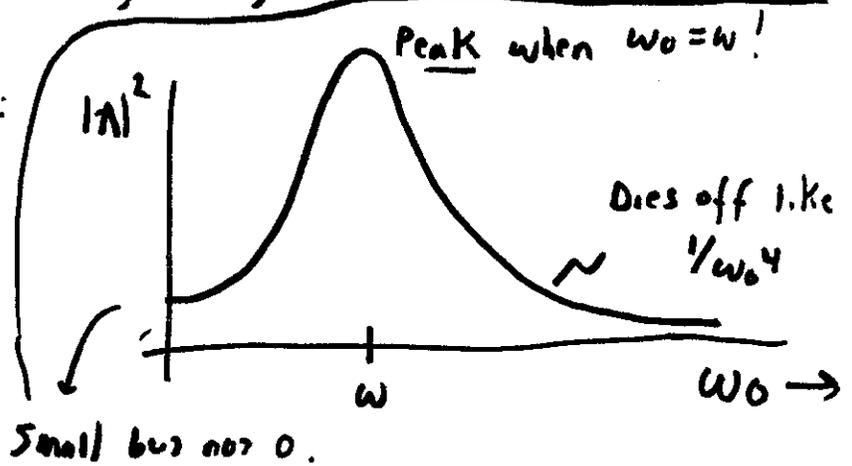

respond? (or, how does $|A|^2$ respond, since that's \propto energy)

OSC -32. (Case 1: Fix ω , vary ω_0)

$$|A|^2 = f_0^2 / ((\omega_0^2 - \omega^2)^2 + 4\beta^2 \omega^2) \quad \text{think of this as a}$$

fn of ω_0 :

$$\frac{1}{c^2 + (\omega_0^2 - \omega^2)^2}$$

The max occurs when denom is min, + that's $\omega_0 = \omega$

If β is small, $|A|^2$ grows very large when $\omega_0 = \omega$, in fact.

$$|A|_{\max}^2 = f_0^2 / 4\beta^2 \omega^2 \quad (\rightarrow \infty \text{ if } \beta \rightarrow 0)$$

This "Blowup" when $\omega_0 \approx \omega$ is Resonance.

The system responds strongly when you drive it at the natural frequency.

(If ω_0 is far from ω in either direction, the response is much weaker)

OSC - 33

(Case 2: Fix ω_0 , vary ω)

$$|A|^2 = f_0^2 / ((\omega_0^2 - \omega^2)^2 + 4\beta^2 \omega^2)$$

Again, MAX occurs when denominator is minimum, i.e.

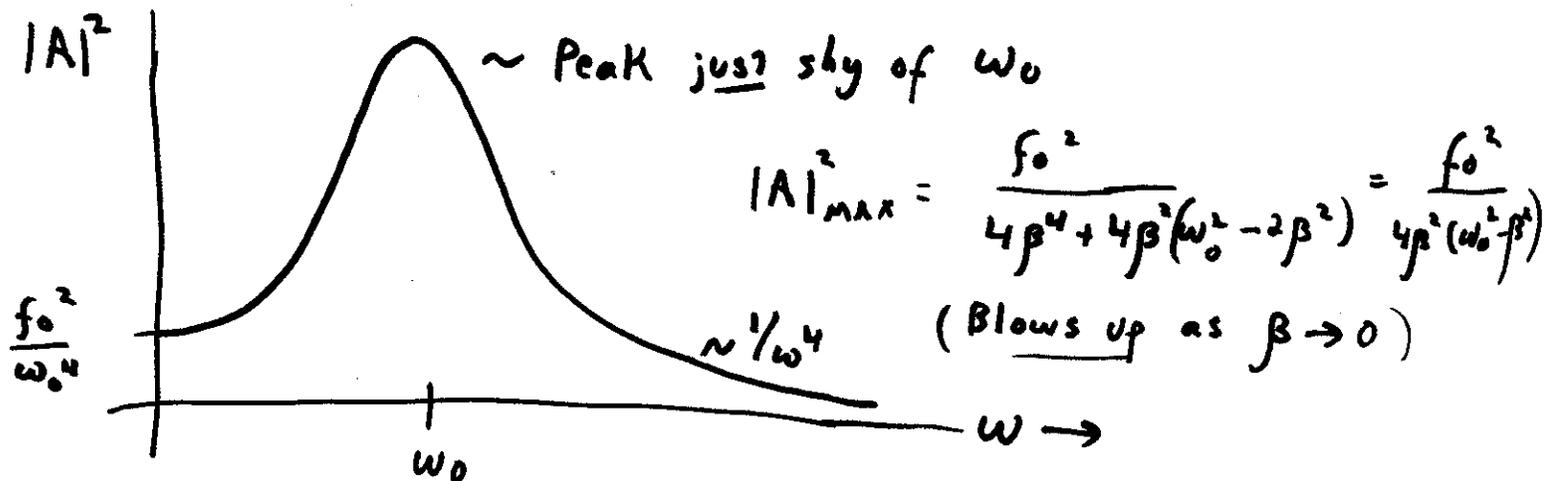

$$\frac{d}{d\omega} (\omega_0^4 - 2\omega^2 \omega_0^2 + \omega^4 + 4\beta^2 \omega^2) = 0$$

$$\text{i.e. } -2\omega_0^2 \cdot 2\omega + 4\omega^3 + 8\beta^2 \omega = 0$$

[$\omega = 0$ solves this, but that turns out to be a max, not a min, of the denominator, at least if $\beta \ll \omega_0$.]

The other sol'n: $\omega^2 - \omega_0^2 = -2\beta^2$ (Divided out ω)

So $\boxed{\omega_{\text{peak}}^2 = \omega_0^2 - 2\beta^2}$ gives "resonant ω "

Again, resonance when $\omega \approx \omega_0$.

osc -34

Summarizing: $\omega_0 = \sqrt{k/m}$ = natural undamped freq.

ω = driving freq

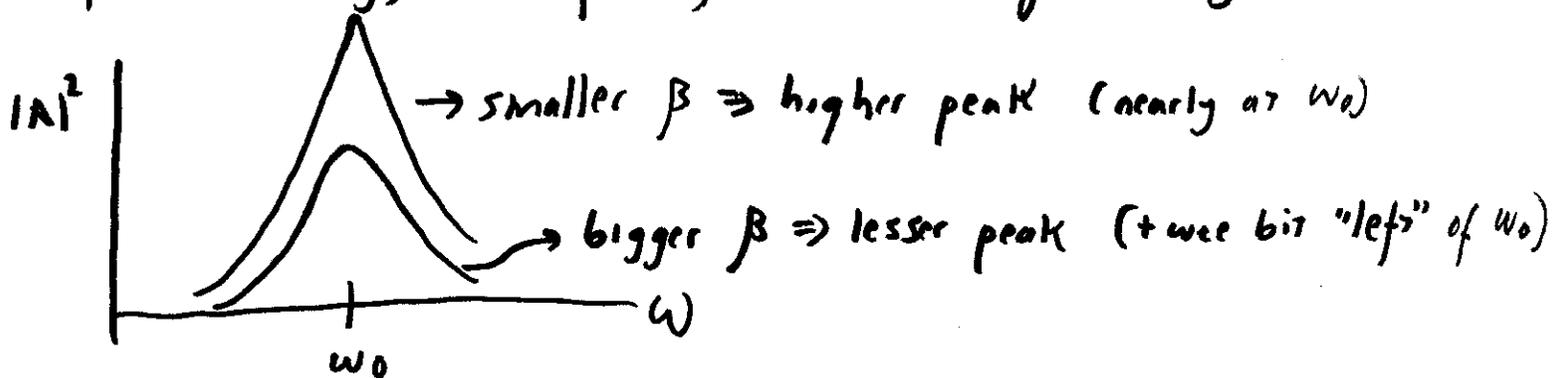

$\omega_1 = \sqrt{\omega_0^2 - \beta^2}$ = nat damped freq

$\omega_{\text{peak}} = \sqrt{\omega_0^2 - 2\beta^2}$ = resonant freq (for fixed ω_0 .)

$$|A_{\text{max}}| \approx \frac{f_0}{2\beta\omega_0} \quad (\text{if } \beta \ll \omega_0)$$

Kids on swings know all this! ω_0 is the "natural swing freq", + you get the best ride if you pump at that freq.

If there's drag, $|A|$ is finite, but can be quite big.

Width of the resonance curve: Let's look for the ω

where $|A^2|(\omega) = \frac{1}{2} |A^2|(\text{peak})$. That's "half max"

it will be (next page) $\omega \approx \omega_0 \pm \beta$.

So, smaller β \Rightarrow taller and narrower resonance.

Osc -35

$$|A|^2 = \frac{f_0^2}{(\omega_0^2 - \omega^2)^2 + 4\beta^2 \omega^2}$$

This is "half max" when
the 1st term = 2nd term

(if β is small) ~~(if β is small)~~

So this is when $\omega_0^2 - \omega^2 = \pm 2\beta\omega_0$

if β is small, $\omega_0^2 - \omega^2$ is thus small, so our

$\omega = \omega_{\text{Half Max}}$ is in fact still very near ω_0 .

In that case $\omega_0^2 - \omega^2 = (\omega_0 + \omega)(\omega_0 - \omega) \approx 2\omega_0(\omega_0 - \omega)$

and $\pm 2\beta\omega \approx \pm 2\beta\omega_0$, so

$$(\omega_0 - \omega) \approx \frac{\pm 2\beta\omega_0}{2\omega_0} = \pm \beta, \text{ as claimed.}$$

Osc - 36

It's common to define a "Quality Factor" $Q \equiv \frac{\omega_0}{2\beta}$
unitless!

Narrow resonance \Leftrightarrow small $\beta \Leftrightarrow$ big Q .

$$|A|_{\text{peak}}^2 \approx \frac{f_0^2}{4\beta^2 \omega_0^2} = \frac{f_0^2 \omega_0^2}{4\beta^2 \omega_0^4} = Q^2 \frac{f_0^2}{\omega_0^4} \propto Q$$

$$Q = \frac{\omega_0}{2\beta} = \frac{2\pi / T_{\text{NATURAL}}}{2\beta}$$

Recall that with no driver,
~~amp~~ $\sim e^{-\beta t}$ dies off
in time $\tau \approx 1/\beta$

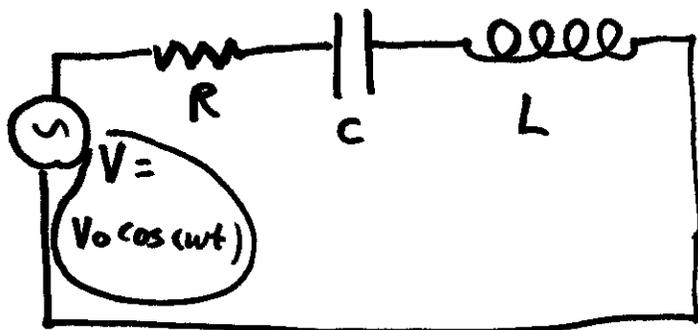

$$\text{so } Q = \pi \frac{\tau}{T_{\text{NATURAL}}}$$

Big Q means "die-off time" is long
compared to natural period.

So, Big Q means you will "Ring" many times without a driver
And, with a driver, you'll get strong resonance.

you can also show Q tells you Energy stored in oscillator
(Energy lost to damping in one cycle)

I've referred to RLC circuits. They might look like this:

Kirchhoff says $\Delta V_{loop} = 0$

$$+V_0 \cos \omega t - IR - \frac{Q}{C} - L \frac{dI}{dt} = 0$$

\uparrow \uparrow \uparrow
 ΔV resistor, capacitor inductor

But $I = dQ/dt$, so

$$L \frac{d^2 Q}{dt^2} + R \frac{dQ}{dt} + \frac{Q}{C} = V_0 \cos \omega t \Rightarrow \text{our usual ODE!}$$

$$\ddot{Q} + \frac{R}{L} \dot{Q} + \frac{1}{LC} Q = \frac{V_0}{L} \cos \omega t$$

\uparrow \uparrow \uparrow
 2β ω_0^2 f_0

R causes damping, makes sense!

$1/LC = \omega_0^2$ is the "natural frequency"

For a 30 pF capacitor
100 nH inductor

$$\Rightarrow f_0 = \frac{\omega_0}{2\pi} = \frac{1}{2\pi\sqrt{LC}} \approx 90.9 \text{ MHz}$$

cheap, simple, ordinary values
